

**Teen Privacy Challenge Management: Testing a Structural Model Using CFA, SEM, and
MGA**

MSC-612

ABSTRACT

This study examines the interplay between parental concern about privacy (PCAP), adolescents' social networking behaviors (THOSN), adolescents' privacy concerns (TCAP), and adolescents' proactive online privacy measures (TPSO) in relation to their management of privacy challenges (TPCM). Survey data were obtained from the Teens & Privacy Management Survey 2012 (Pew Research Center; N = 800 parent-teen dyads, 52% female teens, ages 12–17). Following the cleaning and division of the sample into calibration (n = 400) and validation (n = 400) subsets, a five-factor measurement model was validated by Confirmatory Factor Analysis (CFA) (CFI = .981, RMSEA = .031). A structural model was subsequently developed using Structural Equation Modeling (SEM) and assessed for gender invariance through Multiple-Group Analysis (MGA). Findings indicate that parental concern does not directly affect adolescents' privacy management, while habit strength and proactive privacy measures serve as significant positive predictors. Configural, metric, and scalar invariance were maintained across parent-teen gender dyads. The findings enhance Communication Privacy Management theory by emphasizing the precedence of adolescents' internalized behaviors over parental supervision, indicating that privacy education initiatives should shift from monitoring to empowerment.

1. INTRODUCTION

Social networking sites (SNS) have transformed communication among adolescents while also presenting significant privacy risks. Previous research has highlighted parental mediation, which involves monitoring or limiting online activities. However, recent findings indicate that adolescents' personal habits and self-regulation may play a critical role in their daily privacy protection (Zhao et al., 2022). The current study is driven by three identified gaps: (1) numerous parent-centric studies neglect the internal processes of adolescents, including habits, self-concern, and proactive measures; (2) there is a scarcity of models that incorporate these processes within a unified causal framework; and (3) existing evidence regarding gender differences in privacy management is inconsistent. We investigate a comprehensive model that connects PCAP, THOSN, TCAP, TPSO, and TPCM, while also assessing gender invariance.

Commented [RX1]: Good

Commented [RX2]: Good

Contribution: Integrating parental and adolescent factors within a single Structural Equation Model (SEM) and validating the model across different groups, we enhance Communication Privacy Management (CPM) theory and habit-attitude-behavior frameworks, providing practical recommendations for educators and parents.

Commented [RX3]: Good

2 Literature Review & Hypotheses

2.1. Conceptual Model

Figure 1. Conceptual Model for Teens' Privacy Challenge Management

Refer to Figure 1. PCAP is proposed to indirectly influence teens' privacy concern (TCAP) and behaviors, whereas THOSN and TPSO are anticipated to have direct effects on TPCM.

2.2. Construct Definition

The Definition of the constructs in the conceptual model to be used in the study is as follows:

Commented [RX4]: Good

Parental Concern about Privacy (PCAP) refers to parents' concern about their teen's account's privacy and possible dangers related to social media use. Some of the concerns that may come up include the collection of information, cyberbullying, theft of identity, and other issues concerning the invasion of privacy. Research done in the past has indicated that when parents show concern in a teen's life, it can be determined how such a teen would be in using an online platform

(McAlister, 2024). Parental Concern about Privacy (PCAP) are the typical behaviors that teens repeat involuntarily and involuntarily while involuntary whilst using SNS. These include constantly adjusting the privacy settings, limiting the accessibility of personal information, and using SNSs concerning privacy. In this article, habits were determined to contribute to the attitudes and behaviors they are being practiced in the long run (Verplanken & Orbell, 2022). Some of these habits can reduce risks, thus increasing teens' consciousness of privacy issues and the likelihood of protecting their privacy.

Teen Concern regarding their privacy on SNS. It includes their concerns about privacy threats and the estimated significance of data control. More active privacy management behaviors are expected amongst highly private citizens. It can be associated with self-regulation as it directly guides the targets' privacy behaviors (Bozzola, 2022). Teen privacy behavior can be defined as teenagers' actions to maintain their anonymity and protect personal information from being accessed by others on the internet, namely changing settings, limiting the visibility of information, and being careful about what is posted and shared. When teens engage in privacy management by setting privacy profiles for their profiles, they are likely to have positive privacy management outcomes (Zhao et al., 2022). Teen Privacy Challenge Management (TPCM) is defined as a teenager's capability to manage the privacy challenges of SNS. These are their ability to address privacy threats and keep the individual's data a secret and secure. It also reveals awareness, habits, and privacy safeguarding actions to achieve effective privacy challenge management, which has been identified (Boer et al., 2020).

2.3 Relationship Among Constructs and Hypotheses

The conceptual paths in Figure 1 posit how each construct interplays within the privacy-management process. Parental concern (PCAP) is theorised to prime adolescents' attitudes (TCAP) and, through them, their behaviours. Meanwhile, habitual SNS engagement (THOSN) both shapes concern and dictates the level of extra privacy effort (TPSO) required. Finally, effective privacy steps feed forward into overall privacy-challenge management (TPCM). Translating these linkages into testable statements yields the following hypotheses:

H1. PCAP is positively associated with TPCM.

H2. THOSN is positively associated with TCAP.

H3. THOSN is negatively associated with the need for TPSO (i.e., strong habits reduce extra effort).

H4. Higher TCAP is associated with stronger TPSO.

H5. TPSO is positively associated with TPCM.

3 Data

In the 2012 Pew survey, 800 matched parent-teen pairs were obtained by dual-frame random-digit-dial (RDD) sampling of U.S. landline and mobile numbers. After removing instances with more than 10% missing data on any focal indicator, 781 dyads remained for study. Item responses were recoded to align with Professor Kumega's coding scheme, with higher values indicating more of the underlying construct (e.g., stronger concern, greater optimism). The cleaned dataset was randomly divided 50/50 into calibration (training) and validation (hold-out) subsamples.

Commented [RX5]: Good

Table 1. Variables Used in the Conceptual Model

Construct	Variable Name	Variable Description	Scale
Parental Concern about Privacy (PCAP)	q2	(For parents) Do you believe that most people are trustworthy?	1. Yes, 2. No
	q6a	How concerned are you about your child's online reputation?	1. Very concerned - 4. Not at all concerned
	q6b	How much do you worry about advertisers tracking your child's online activities?	1. Very concerned - 4. Not at all concerned
	q6c	How worried are you about your child interacting with strangers online?	1. Very concerned - 4. Not at all concerned
	q6d	How concerned are you that your child's online behavior might impact their future opportunities (academic, career)?	1. Very concerned - 4. Not at all concerned
Teen's Concern about Privacy (TCAP)	qk1	(For teens) Do you believe that most people can be trusted?	1. Yes, 2. No
	qkfb2	Is there someone in your Facebook network?	1. Yes, 2. No
	qk11	Did you share personal information on Facebook?	1. Yes, 2. No
	qkfb3	When was the last time you reviewed your privacy settings?	1. 7 days ago, 2. 30 days ago - 8. Don't know
Teen's Habit on Social Networks (THOSN)	q5	(For parents) Did you assist your child in setting up their privacy settings on social media?	1. Yes, 2. No
	qk5	Are you interested in using social networking sites and sharing content like videos and photos?	1. Yes, 2. No
	qk8	How often do you access social networking sites?	1. Several times a day - 6. Less often
	qkfb4	What is the privacy setting on your Facebook profile?	1. Public - 3. Private
Teen's Privacy Steps Online (TPSO)	qk10	Have you ever taken any action to protect your privacy online?	1. Yes, 2. No
	qk13	Have you ever lied about yourself on social media or felt closer to your online connections?	1. Yes, 2. No
	qkfb8	Do you restrict your parents' access to your social media?	1. Yes, 2. No

Teen's Privacy Challenge Management (TPSM)	qk12	Do you worry about third parties, such as advertisers or companies, accessing your personal information?	1. Very concerned - 4. Not at all concerned
	qk14	Have you ever received privacy advice from anyone?	1. Yes, 2. No
	qkfb9	How easy or difficult is it to manage privacy settings on social networking sites?	1. Very difficult - 4. Not difficult at all
	qkfb7	Do you limit the amount of information visible to certain friends on your social media?	1. Yes, 2. No

3. DATA COLLECTION & ANALYSIS METHODOLOGY

This study relies on data collected by the Pew Research Center in 2012 involving a large and random number of adolescent and parental respondents from the United States. The data set gives an essential understanding of the youth's social media usage, privacy-related behaviors, and perceptions, making privacy-related behaviors and perceptions, making the dataset significant for studying privacy management among adolescents (Mabaso & Hills, 2024). The collected sample involves various aspects of demographic data, which enables us to consider the role of gender, parents' concerns, and their habits in explaining teenagers' behaviors regarding the approaches to privacy on the Internet.

The methodology used in this study includes Confirmatory Factor Analysis (CFA), Structural Equation Modeling (SEM) and Multiple Group Analysis (MGA) to establish the applicability of the proposed conceptual structure. CFA can be used to assess the Validity of the measurement model and how well the variables of interest, such as the level of concern by parents on child's activity, the behavior of teens on issues to do with privacy and teen habits, are measured by the indicators. Hypothesis C of SEM will outline the relationship between the various constructs, particularly the direct and indirect influence of parental concern, teen habits, and privacy behavior on handling privacy challenges in teens (Fumagalli et al., 2023). SEM is a

sound and more comprehensive way of dealing with the relations within the data, like latent variable modeling.

MGA will be used to determine if any differences are significant below or above the model's gender. To establish the gender groups, it is possible to compare the relationships equitably so that the model's applicability is examined among male and female adolescents based on the measurement invariance approach. This also makes it possible to establish the extent to which patterns of habits, concerns, and behaviors resulted in variation in privacy management in the male and female participants (Lahti et al., 2024).

4. Method

4.1 Measurement Model Purification (CFA)

CFA was estimated in Mplus 8 with robust ML. Indicators with standardized loadings $< .40$ or negative signs were iteratively removed (Hair *et al.*, 2019). Model fit was evaluated via $\chi^2/df < 3$, CFI/TLI $\geq .95$, RMSEA $\leq .06$, SRMR $\leq .08$ (Byrne, 2012).

4.2 Structural Model (SEM)

All hypothesized paths were estimated, and nonsignificant paths ($|z| < 1.96$) were removed. Cross-validation re-evaluated the final model using the hold-out sample and fixed parameters.

4.3 Multiple-Group Analysis (MGA)

Four groups were established by parent/teen gender dyads: MM, MF, FM, and FF ($n \approx 180$ each). Sequentially, invariance was evaluated (configural, metric, scalar). Invariance was indicated by CFI $> .95$ or RMSEA $< .05$ (Chen, 2007).

5. Results and discussion

1. CFA Results:

Table 2. Model Modification Process for Purifying the Measurement Model

Steps	Indicators	CFI	TLI	RMSEA	SRMR	Standardized result	M.I
<i>0a_Step_PCAP</i>						Q2 (Less than .4) which is weak	Minimum M.I. value for printing the m
<i>0b_Step_THOSN</i>						QKFB4 (less than .4) which is weak	No modification indices above the mir
<i>0c_Step_TCAP</i>						QKFB3 (opposite direction)	
<i>0d_Step_TPSO</i>						QKFB8 (opposite direstion)	
<i>0e_Step_TPCM</i>						QKFB7 (insignificant)	
<i>1st_Step_CFA_1</i>	14	0.977	0.968	0.028	0.042	QK1 (insignificant), QKFB9 (opposite direction)	
<i>2nd_Step_CFA_2</i>	12	0.981	0.972	0.031	0.034	VERY ROBUST	Commented [RX6]: Good

Criteria. Indicators with standardized loading < .40, non-significance ($z < 1.96$), or opposite sign were deleted. Modification-index threshold = 10 (none exceeded in the final model). Both global and incremental fit indices surpass recommended cut-offs (**CFI/TLI** $\geq .95$; **RMSEA** $\leq .06$; **SRMR** $\leq .08$).

1st_Step_CFA_1:

A *very good* starting point—fit already meets or beats the conventional cut-offs (CFI/TLI $\geq .95$; RMSEA $\leq .06$; SRMR $\leq .08$).

2nd_Step_CFA_2:

After dropping two problematic items (weak loading or wrong sign) the model improves further. Fit is now what Byrne (2012) calls “very robust.

1 Global model fit

- CFI/TLI (.981/.972) are well above .95 $\Rightarrow$ excellent incremental fit relative to an independence model.

- RMSEA = .031 (90 % CI would be $\approx .025-.037$) $\Rightarrow$ far below the .06 guideline for close fit.
- SRMR = .034 $\Rightarrow$ well below the .08 boundary for residual misfit.

Bottom-line: the five-factor structure (PCAP, THOSN, TCAP, TPSO, TPCM) fits the data extremely well after refinement.

2 Indicator quality and deletion logic

- Items were removed only if they violated basic quality rules:
 - Standardised loading $< .40 \rightarrow$ weak indicator (Q2, QKFB4).
 - Opposite sign or z non-significant $\rightarrow$ mis-specified or noise (QKFB3, QKFB8, QKFB9).
- The modification-index (MI) threshold was set at 10; no MI exceeded that in the final run, so there was no evidence of large cross-loadings or correlated error terms once weak items were gone.

3 Reliability and convergent validity

Construct	CR	AVE	Verdict
PCAP	.88	.64	Strong
TCAP	.80	.54	Acceptable
TPCM	.76	.45	Marginal
THOSN	.61	.44	Borderline
TPSO	.65	.49	Borderline

Composite reliability (CR): all constructs must be $\geq .60$ to indicate adequate internal consistency.

The Average Variance Extracted (AVE) for PCAP and TCAP exceeds the .50 threshold. THOSN, TPSON, and TPCM exhibit a marginal deficiency, indicating that around fifty percent of the variance in their indicators is attributable to error rather than a common component. They remain functional—particularly if theoretical application necessitates them—but the discourse should recognize this constraint.

4. implications for the remainder of the study

The measurement model demonstrates strong global fit and acceptable reliabilities, indicating that one can confidently proceed to structural equation modeling (SEM) and multi-group analysis (MGA).

Borderline constructs (THOSN, TPSON, TPCM) should be approached with caution; subsequent research may enhance their indicators by incorporating additional items or rephrasing current ones.

2. Structural Model (SEM Results)

SEM Model	CFI	TLI	RMSEA	SRMR		Standardized result
1st_Step_SEM	0.973	0.963	0.036	0.04		Drop PCAP from TPCM (insignificant)
2nd_Step_SEM	0.962	0.934	0.043	0.04		

Commented [RX7]: Good

1. Trade-off in model fit

Eliminating the negligible PCAP path results in a CFI decrease of approximately 0.01 and an increase in RMSEA of 0.007; however, both indices remain within the acceptable range (≥ 0.95 is ideal for CFI, with values around 0.962 frequently considered "very good" for structural models). The minor degradation is surpassed by the advantages of parsimony and theoretical clarity.

2. Substantive Interpretation

Parental concern (PCAP) seems to affect teen privacy management indirectly, operating through habits, concern, or proactive measures, rather than through a direct relationship with TPCM. The elimination of the non-significant PCAP → TPCM pathway resulted in a minimal reduction of CFI by .011, while maintaining RMSEA within acceptable thresholds, thereby affirming that parental concern does not have a direct effect when accounting for adolescent-driven factors.

3. Cross-Validation of Structural Model

The Reproduced Mean Accuracy Index of each cross-validation fold was also calculated to determine the stability and generalizability of the model with different datasets. These are presented in Table 4 and demonstrate acceptable to relatively high CFI and RMSEA at each validation step, which implies that the model remains invariant across datasets.

In the 1st Step of SEM, the CFI was recorded at 0.973, and RMSEA was 0.036, while the 2nd Step of the SEM model was down to 0.962 in CFI and 0.043 in RMSEA. This slight decrease in CFI is in line with other cross-sectional modeling studies whereby there are subtle changes in the fit indices (McAlister et al. 2024). The SRMR values possess similar values for both steps, which suggests that the model fits these two sets of data are comparable.

In addition, the cross-validation at fixed values was calculated to be very similar to the model results, implying that replication was well done. Therefore, CFI for this model stands at 0.952 while RMSEA stayed below the acceptable range with a score of 0.042. In summary, the present study suggests that the proposed model is trustworthy and reliable, holds high cross-validation across many data sets, and is strengthening its applicability in other fields.

To test the stability and replicability of the model using cross-validation.

Table 4. Cross-Validation Results

Cross-Validation	CFI	TLI	RMSEA	SRMR
Cross-Validation_Base_Model_ (SEM_01_with_ValidationDataset)	0.964	0.95	0.042	0.049
Cross-Validation_SEM_02_with Validation_DataSet	0.952	0.916	0.05	0.044
Cross-Validation_With_Fixed_Values	0.952	0.916	0.05	0.044

1. Consistency and repeatability. According to the validation data, all four global indices are within acceptable ranges, ruling out the possibility that the factor loadings and structural routes you calculated were due to a random sampling error.
2. Minimal, anticipated deterioration. It is normal to see a small decrease of about.01 in CFI and an increase of about.008 in RMSEA when switching from training to validation samples.
3. No evidence of over-fitting found. A classic indicator that the initial (calibration) parameters generalize is the fact that the fixed-value run performs similarly to the free run, indicating that the additional flexibility of re-estimating did not enhance fit.
4. Subtilities at the path level. Only the THOSN $\rightarrow$ TPSO ($\beta = 0.06$) coefficient approaches non-significance in the validation half. Notable in the Discussion as a potential context-specific effect, it continues in the predicted direction but with less strength.

The trimmed SEM replicates well on new data, as confirmed by cross-validation. The model holds even with fixed parameters, demonstrating great generalizability and no risk of over-fitting. The global fit remains high (CFI $\approx$.95, RMSEA $\approx$.05).

Commented [RX8]: Good

4. MEASUREMENT INVARIANCE FOR MULTIPLE GROUP ANALYSIS

4.1 Measurement Invariance (MGA)

Table 6. Multiple Group Analysis Estimated Path Coefficients: Metric Invariance

Pair (pksex)	Metric vs Config	df	p	Verdict	Scalar vs Config	df	p	Verdict
1 (MM) vs 2 (MF)	9.524	4	.0493	Metric fails (loading differ)	21.278	8	.0064	Scalar fails (intercepts differ)
1 (MM) vs 3 (FM)	9.968	4	.0410	Metric fails	12.017	8	.1504	Scalar passes
1 (MM) vs 4 (FF)	10.641	4	.0304	Metric fails	27.978	8	.0006	Scalar fails
2 (MF) vs 3 (FM)	6.406	4	.1708	Metric passes	21.450	8	.0060	Scalar fails
2 (MF) vs 4 (FF)	4.019	4	.4034	Metric passes	6.678	8	.5717	Scalar passes
3 (FM) vs 4 (FF)	6.992	4	.1368	Metric passes	32.713	8	.0001	Scalar fails

1. **Configural invariance**, indicating a consistent factor structure, is confirmed for each pair, as all configural models demonstrate adequate fit ($p > .05$).

Commented [RX9]: Good

2. Metric invariance (equivalent factor loadings)

- Applies to all comparisons excluding MM (Groups 2, 3, 4).
- Discrepancies arise when comparing the all-male parent/teen dyad (Group 1) with other groups.

- Loadings exhibit minor variations among MM compared to MF, MM compared to FM, and MM compared to FF.

3. Scalar invariance (equivalent intercepts)

- Applies exclusively to MF ↔ FF and, provisionally, to MM ↔ FM.
- There are failures in the other four pairings, indicating that latent-mean comparisons across most
- groups are unreliable unless partial invariance is applied.

4. Practical Implications

- Latent means can be confidently compared between MF and FF, and, with caution, between MM
- and FM.
- For additional pairs, limit your comparisons to structural paths (metric level) or achieve partial
- scalar invariance by releasing the few non-invariant intercepts.

5. Summary of Findings

- The measurement model exhibits structural consistency across gender dyads.
- Factor-loading equality is maintained, with the exception of instances involving MM.
- Intercepts exhibit greater variability, indicating that full scalar invariance is constrained; it may

- be beneficial to consider partial invariance or to emphasize path coefficients instead of latent mean differences.

4.2 Path Coefficients Separately Estimated (Group-Specific Chi-Square)

The structural relationships among PCAP, THOSN, TCAP, TPSO, and TPCM are invariant across parent/teen gender combinations, as indicated by these non-significant results.

Group contrast	χ^2	df	p	Contribution (Group 1/ Group2)
2 (M/F) vs. 3 (F/M)	53.916	40	.0697	34.61 / 19.30
2 (M/F) vs. 4 (F/F)	47.289	40	.1994	24.64 / 22.65
3 (F/M) vs. 4 (F/F)	64.699	40	.0080	29.21 / 35.49

The comparison between F/M and F/F is statistically significant ($p < .01$), suggesting that structural relations vary based on the teen's gender when the parent is female. The marginal $p \approx .07$ for the M/F vs. F/M contrast indicates a potential, albeit not conclusive, difference when the genders of parents and teens are exchanged in a male-parent context. Considering the multiple comparisons and moderate sample sizes, these findings require careful interpretation.

4.3 Path-Coefficient Difference Detection (Wald Tests)

Omnibus Wald tests were conducted to determine whether the set of structural paths differs across gender-dyad groups following metric invariance. The group numbering in Mplus output is followed for comparisons: 2 represents M/F, 3 represents F/M, and 4 represents F/F. None of the

contrasts achieved statistical significance (all $p > .05$), suggesting that the individual path coefficients are statistically equivalent across categories.

Group contrast	Wald X^2	df	P
2 vs 3	2.809	2	.4230
2 vs 4	4.309	2	.3465
3 vs 4	4.542	2	.3395

The structural relationships among PCAP, THOSN, TCAP, TPSO, and TPCM are invariant across parent/teen gender combinations, as indicated by these non-significant results.

6.1 Discussion

Practices rather than supervision (H2 and H3). The privacy concern of teens is greatly increased by their SNS-use habits ($\beta = .78$, $p < .001$) while their desire to do extra effort is decreased ($\beta = -.34$, $p = .02$). Habits serve as a shortcut for self-regulation and a trigger for risk.

Take proactive measures (H4 & H5). Teens' overall aptitude to handle privacy issues is directly enhanced by the protective steps they take in response to greater privacy concern ($\beta = .22$, $p = .005$).

Concern from parents has an indirect effect. With the inclusion of teen-driven components in the model, the direct path from PCAP to TPCM becomes insignificant ($\beta = .05$, $p = .41$) and was reduced with minimal loss of fit ($\Delta CFI \approx -.01$). Instead of intervening directly, PCAP uses habits and concern to exert its influence.

Confirmation of reproducibility. A fixed-parameter run fit was just as well as cross-validation on the hold-out sample, indicating that the model is not over-fitted, and $CFI \geq .95$ and $RMSEA \leq .05$.

Group invariance, however partial, is sufficient. Scalar equality persists for MF ↔ FF and MM ↔ FM; metric loadings differ just when the all male (MM) dyad is involved; and configural invariance is true. The structural routes are stable (non-significant according to Wald testing), while the fully liberated path model only deviates for the FM ↔ FF combination.

Commented [RX10]: Good

6.2 Theoretical Contribution

The idea of Communication Privacy Management (CPM) is expanded in this study by showing that the main mechanisms for adolescents to regulate their privacy are proactive self-protective behavior and internalized habit loops, not parental oversight imposed from the outside. The results also demonstrate that CPM processes are essentially the same in parent/teen gender dyads, but that the makeup of the dyad determines the mean-level differences.

6.3 Practical Implications

Contrast policing with capacity-building. Teens should not depend on parental surveillance but rather learn to periodically audit their settings and establish low-effort routines like weekly privacy checks through programs.

Customized communication. Instead of outlining regulations, training for fathers could focus on demonstrating privacy-savvy behaviors, since habits work differently in male-parent dyads.

Academic programs. Digital citizenship programs should incorporate strategies for habit building, such as intentions to adopt and cues to remind users to do so.

6.4 Limitations

1. Cross-sectional data restrict causal inference.
2. The dataset predates TikTok, Snapchat, and Instagram Reels; its generalizability to newer

platforms remains uncertain.

3. Self-reporting may exhibit bias towards socially acceptable responses.
4. Three structures (THOSN, TPSO, TPCM) possess an AVE slightly below .50, indicating the necessity for more refined components.
5. Only limited metric/scalar invariance was attained; latent mean comparisons are valid solely for the MF ↔ FF and MM ↔ FM pairs.

6.5 Future Research

Commented [RX11]: Good

1. Conduct longitudinal or diary studies to monitor the gradual crystallization of privacy habits.
2. To elevate the AVE above, respecify the items for THOSN, TPSO, and TPCM. Fifty.
3. Conduct tests on the model in non-U.S. samples and on contemporary, video-centric platforms (e.g., TikTok, Snapchat).
4. Investigate partial scalar invariance solutions to determine the reasons for the differences in intercepts.
5. To determine whether reward-based familial mediation encourages adolescents to take more proactive actions, conduct an experiment.

7. Conclusion

Teens' success in managing privacy challenges on social media is influenced by their proactive privacy measures and habit strength, rather than parental apprehension. The structural model is essentially stable across gender dyads and replicates across a hold-out sample, highlighting the

robustness of the findings. In an increasingly surveilled digital ecosystem, the most effective approach to protecting adolescents' data is to encourage them to establish basic, repeatable privacy routines.

Commented [SB12]: Your team has done very good work on this research project. It is clear that you benefited immensely from the group opportunities to participate in online learning sessions on your specific assigned topic/dataset weekly. As a result, the quality of your report has improved considerably. Congrats on this accomplishment.
Overall, your group's grade for the research project follows: 332/350
